Using **expm** in packages

1 Introduction

The \mathbf{expm} package provides an R function \mathbf{expm} to compute the matrix exponential of a real, square matrix. The matrix exponential of a matrix \mathbf{A} is defined as

$$e^{\mathbf{A}} = \mathbf{I} + \mathbf{A} + \frac{\mathbf{A}^2}{2!} + \dots$$

= $\sum_{k=0}^{\infty} \frac{\mathbf{A}^k}{k!}$.

The actual computations are done in C by a function of the same name that is callable by other packages. Therefore, package authors can use these functions and avoid duplication of efforts.

2 Description of the functions

The R function expm takes as argument a real, square matrix and returns its exponential. Dimension names are preserved:

A B C a 4 2 0 b 1 4 1 c 1 1 4

> expm(m)

A B C
A 147.8666 183.7651 71.79703
B 127.7811 183.7651 91.88257
C 127.7811 163.6796 111.96811

Note that the remainder of this text **mainly** relates to expm(., method = "Ward77"), i.e., the method of Ward (1977) which is no longer the default method, as e.g., method = "Higham08" has found to be ("uniformly") superior, see Higham (2008).

The actual computational work is done in C by a routine defined as

void expm(double *x, int n, double *z)

where \mathbf{x} is the vector underlying the R matrix and \mathbf{n} is the number of lines (or columns) of the matrix. The matrix exponential is returned in \mathbf{z} . The routine uses the algorithm of Ward (1977) based on diagonal Padé table approximations in conjunction with three step preconditioning. The Padé approximation to $e^{\mathbf{A}}$ is

$$e^{\mathbf{A}} \approx R(\mathbf{A}),$$

with

$$R_{pq}(\mathbf{A}) = (D_{pq}(\mathbf{A}))^{-1} N_{pq}(\mathbf{A})$$

where

$$D_{pq}(\mathbf{A}) = \sum_{j=1}^{p} \frac{(p+q-j)!p!}{(p+q)!j!(p-j)!} \mathbf{A}^{j}$$

and

$$N_{pq}(\mathbf{A}) = \sum_{i=1}^{q} \frac{(p+q-j)!q!}{(p+q)!j!(q-j)!} \mathbf{A}^{j}.$$

See Moler and Van Loan (1978) for an exhaustive treatment of the subject. The C routine is based on a translation made by ? of the implementation of the corresponding Octave function (Eaton, 2002).

3 Calling the functions from other packages

Package authors can use facilities from **expm** in two (possibly simultaneous) ways:

- 1. call the R level function expm in R code;
- 2. if matrix exponential calculations are needed in C, call the routine expm.

Using ${\sf R}$ level function ${\sf expm}$ in a package simply requires the following two import directives:

```
Imports: expm
in file DESCRIPTION and
import(expm)
in file NAMESPACE.
```

Accessing the C level routine further requires to prototype expm and to retrieve its pointer in the package initialization function R_init_pkg , where pkg is the name of the package:

The definitive reference for these matters remains the $\mathit{Writing}\ R\ \mathit{Extensions}$ manual.
